JWT

What is JWT, and what is it used for?

JWT stands for JSON Web Token, It is a token used for authentication and authorization in applications, especially REST APIs

It’s main purpose is to verify the user's identity without needing to store a session on the server for every user

example for how JWT works:

In Spring Boot, when the server generates a JWT using HS256, it uses a secret key to sign the token. When the server receives the token again, it verifies the signature using the same secret key. If the token's content has been tampered with, the signature verification will fail
